High-Sensitivity C-Reactive Protein (hsCRP)

hsCRP levels (1–10 mg/L) are associated with:
- Cardiovascular disease (CVD)
- Periodontal disease

hsCRP levels (>10 mg/L) are associated with:
- Acute illness (cold, flu, or infection)
- Chronic illness
- Autoimmune disorders

Description
The hsCRP test is a highly sensitive quantification of C-Reactive Protein (CRP), an acute-phase protein released into the blood by the liver during inflammation. Elevations in CRP may occur due to instances such as illness, trauma, or surgery. Increased sensitivity allows for detection of low-level elevations of CRP, which are associated with the presence of CVD.

Clinical Use
The hsCRP test may be performed on individuals at intermediate risk (10-year risk of 10%-20%) of developing CVD who are metabolically stable without inflammatory or infectious conditions.

Clinical Significance
- hsCRP is a well-documented clinical marker of general and cardiac-related inflammation.
- Apparently healthy individuals with elevated hsCRP values are up to 4x as likely to have coronary heart disease (CHD).
- Elevated hsCRP is associated with the risk of future adverse cardiovascular events (heart attack, stroke, and death) in apparently healthy individuals, individuals with stable coronary artery disease, or individuals who have previously experienced a heart attack.
- Reductions in both hsCRP and low-density lipoprotein (LDL) cholesterol are associated with a reduction in the rate of atherosclerosis progression and improved clinical outcomes.
- In the JUPITER trial, introduction of statin therapy in patients with elevated hsCRP, even with normal lipid levels, significantly reduced risk for heart attack, stroke, and death.
- The CANTOS trial demonstrated that lowering hsCRP, independent of lipid levels, resulted in a 15% risk reduction of recurrent cardiovascular events.

Testing Frequency
The frequency of testing is determined by an individual’s medical history, but an elevated hsCRP level should be confirmed with an additional measurement. Levels >10 mg/L may reflect acute infection, systemic inflammatory processes, or trauma. Therefore, the American Heart Association and Center for Disease Control and Prevention recommend that the test is repeated in 2-3 weeks to allow acute inflammation to subside, with the lower value, not the average, used for risk prediction.

Sample Type
The hsCRP test should be performed on a serum or EDTA plasma sample. Fasting is not required.

Commercial Insurance or Medicare Coverage
Coverage guidelines, also known as NCD (National Coverage Determination) or LCD (Local Coverage Determination), have been established or posted by CMS (Medicare & Medicaid). Guidelines should be reviewed for coverage and limitation. Limited information has been provided by the majority of the larger carriers (Aetna, United Healthcare, Cigna, Blues).
Treatment Considerations†

These treatment considerations are for educational purposes only. Specific treatment plans should be provided and reviewed by the treating practitioner.

Assess presence of acute (infection, surgery, trauma, etc.) or chronic illness (chronic obstructive pulmonary disease, rheumatoid arthritis, cancer, etc.).

- Assess lifestyle habits.
  - Consider diet, exercise, and weight reduction efforts if appropriate.†
- Assess LDL-C levels.
  - If not at optimal levels, consider lipid-lowering therapies described in the National Cholesterol Education Program/Adult Treatment Panel III (NCEP ATP III) Guidelines. If not contraindicated, statin-based therapy has shown a wide range of biological effects, such as reducing CRP.
- Assess blood pressure.
  - If not at optimal levels, consider initiating, or titrating antihypertensive therapy.†
- Assess clotting risk.
  - Consider antiplatelet medication if history of coronary artery disease (i.e., myocardial infarction or revascularization) and/or a history of cerebrovascular disease (i.e., transient ischemic attack or stroke).

Assess the presence of coronary artery disease with imaging techniques such as carotid intima-media thickness (CIMT) testing or coronary artery calcium (CAC) scoring.

- Assess dental health (periodontal disease).
  - Refer to dentist to identify gum disease. Poor dental health may cause significant inflammation and is associated with the presence of atherosclerosis.†
